

CS551Q Database-Driven Django Application Design and Development Team Delta Group Report

A database-driven Django web application with an assigned carbon dioxide (CO2) emission dataset[1] is developed. There are five steps in the web development process assessing, planning, developing, testing and deploying[2]. In the assessing and planning stages, we worked as a group on requirements studying and model designing with a two-week limit for the whole project. Requirements from the professor were frequently revisited. Model and front-end sketches (Appendices 1.1-1.4) were done together to start with shared understanding.

With limited developing time, Agile Development Methodology[3] with continuous integration (CI) and continuous deployment (CD) were used to implement iterative and incremental development and delivery[4]. We searched for websites using similar datasets[5] and took inspiration from their data visualisation methods. Plan Do Check Act[4] cycle is used for continuous improvement. The project is split into small tasks with expected outcomes during Plan. After coding during Do, we compared the results obtained with the desired output in Check. After getting the desired result, we push the code to GitHub for version control and repeat with the next feature.

The developing stage is separated into two major parts which are the design and implementation of the database and frontend pages respectively. There are three versions of the database. To satisfy the 2000-7000 data rows requirement, 6032 rows of CO2 emission data for 235 countries for 26 years (1996-2021) in each Comma-Separated Values (CSV) file are chosen. These data are stored in 2 separate CSV files in the data folder for ease of data parsing. The country field also has a separate CSV file to save every unique country value from the other CSV files. In the first version, four models are designed where the country is a separate model which acts as the foreign key linking other models: total emission, per capita emission and source. In the second version, id is added to every model and country_id becomes the foreign key. In the third version, a year model storing numbers from 1996-2021 is added for filtering. Four Class objects are defined: Year, Country, TotalEmission and PerCapitaEmission. Year class is the year included with range 1996-2021. Country shows the countries, incidents or global with produced CO2 emissions. TotalEmission gives the total CO2 emissions by different sources (such as coal, gas, and oil) from different countries annually. PerCapitaEmission gives the per capita CO2 emissions by different sources (such as coal, gas, and oil) for different countries. parse_csv.py is written for parsing the data from CSV into the database after removing all data in the original tables. Pair programming[6] is used when writing models.py. Simple HTML & CSS templates are created to verify items parsed into the database (Appendix 2.1). There are three versions for the front end. The website's basic layout is developed in the first version (Appendix 2.2) with a basic landing page, total and per capita CO2 emission page showing all the data in tables using pagination, with map and graph tabs. The second version (Appendix 2.3) was obtained after adding all the developed features such as filtering and graph display functions. The third version (Appendix 2.4) is obtained after changing the background image and solving some pagination issues from the search function, also removing the unused part like the map page and adding a data visualization part for showing both graphs together. The landing page composes of a navigation bar with a title. Data visualization was presented in form of tables, line graphs and bar charts. All forms are available for both total and per capita CO2 emission datasets. The table displays the CO2 emissions by different countries from 1996 to 2021; with a search button for year or country. The line graph and bar chart displays the total and per capita CO2 emissions by country over time. It is switched with a button toggle. By selecting a specific country and material, graphic historical CO2 data over time can be seen. Group collaboration is done explicitly in the front-end development, especially in the final development stages. Pair programming[6] during the development of the filter function (Appendix 1.5) at a faster pace[7] referencing some online reference materials[8].

Model-template-view(MTV) pattern, the Django version of the model-view-controller(MVC) pattern, is applied in the implementation. Model is the database of 5 tables, templates (frontend HTML) are created in the templates/emission folder in the emission application following the Django convention and view is the controller (views.py) controlling all functions implemented[9].

For the implementation stage, we created a Django project (mysite) and application (emission), configured Django settings to include Chart.js library, created models for emissions in countries and years with Django ORM, created views for line graph and bar chart using Chart.js library, created templates and URLs for the table, line graph and bar chart using HTML and Chart.js.

For the testing stage, unit tests that come with Django are mainly used. Five test types (model testing, index testing, graph testing and web views testing) and eleven test items are implemented. Five test types are separately stored in the tests folder. First, the index test tests whether different pages can be accessed and connected. The main method uses response.status_code=200[10] to verify the page connectivity. Second, model testing is for four models: Year, Country, TotalEmission, PerCapitaEmission. Models are tested with different data inputs, with importing models at the beginning. Third, the web view test focuses on the successful loading of the form and checking the form content, by creating test data and using assertContains to determine whether the form contains the test data. Fourthly, the filter test, is mainly to test that the selection component and the button component work properly and that the drop-down menu of the selection component contains the correct option data. The last test is the chart test, which is the same as the home page test, except that it adds the ability to jump to a chart with the correct id, e.g. id=myChart, and detects whether the page contains certain fields to jump to the correct page. All the testing is done based on Django's unit tests.

For the deployment stage, Render is used to deploy the Django application; a cloud platform that offers a simple way for web application deployments. Render deployment was done in the first week of website development for CD by solving some errors earlier(Appendix 5).

GitHub is used throughout the development process and everything is pushed to GitHub when finishing a version of the current feature we are working on, implementing CI. A separate master branch is created for storing the workable copy of the code that everyone agreed on (Appendix 3.3-3.4). However, we still encountered a major Git clash in the final development stage which is solved with the help of other classmates by deleting some messed up commits which are caused by pushing all code (git add .) to GitHub before pulling the latest version (git pull). We have learnt to only push the required or amended files to GitHub after this incident and always git pull before git add any files.

In conclusion, we have learnt everything from assessing to deploying a database-driven Django web application with a filtering function and showing visual graphs. Group collaboration and pair programming are practised during the development process. Data filtering and visualisation are studied and applied. The importance and practices of version control are reintroduced. Unit tests are applied and Render is used for website deployment.

2.2.Version 1

Global CO2 emissions from fossil fuels

Per capita By country By sector

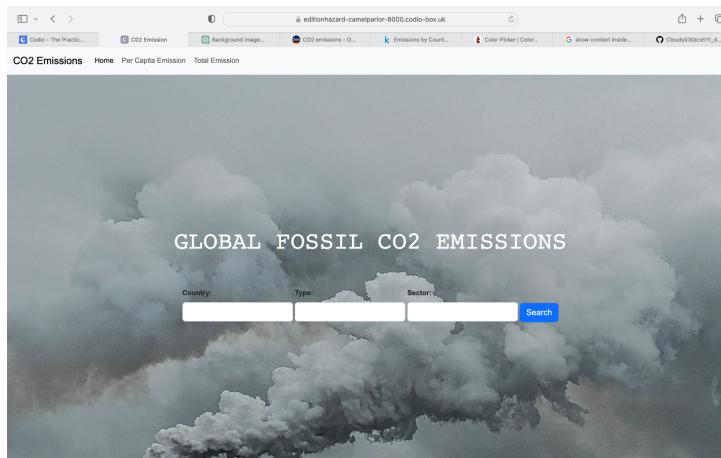

Carbon dioxide emissions are the primary driver of global climate change. It's widely recognised that to avoid the worst impacts of climate change, the world needs to urgently reduce emissions. But, how this responsibility is shared between regions, countries, and individuals has been an endless point of contention in international discussions. This debate arises from the various ways in which emissions are compared: as annual emissions by country; emissions per person; historical contributions; and whether they adjust for traded goods and services. These metrics can tell very different stories. We teamed up with the YouTube channel, Kurzgesagt, to produce a video which explored these different metrics in detail: "Who is responsible for climate change? – Who needs to fix it?". All of the data and research featured in this video is contained in this article; below we look in detail at the many ways emissions are broken down. Co2 kurzgesagt "Who is responsible for climate change? – Who needs to fix it? We teamed up with YouTube channel Kurzgesagt to make a video on comparisons of CO2 emissions. This page is just one in our collection of work on CO2 and Greenhouse Gas Emissions. The rest can be explored via the navigation menu at the top of this page. There you can explore emissions of other greenhouse gases; where our emissions come from; what trajectories of future emissions look like; and what is driving emissions across the world. In the navigation menu you also find Country Profiles, so you can see how your country is doing in reducing emissions, and our CO2 Data Explorer where you can browse all of these metrics in one place.

2.4.3.TotalEmission page filter year

Understanding Total Carbon Dioxide Emissions

Carbon dioxide (CO₂) emissions are a major contributor to climate change, and understanding their impact and trends is crucial for addressing the issue. This chart shows the growth of global CO₂ emissions from the mid-18th century to today.

Before the Industrial Revolution, emissions were very low. However, emissions began to increase rapidly in the mid-19th century, coinciding with global emissions reaching 3 billion tonnes of CO₂ in 1850. By 1950, emissions had almost quadrupled, reaching more than 22 billion tonnes. Today, we emit over 34 billion tonnes of CO₂ each year.

Although emissions growth has slowed in recent years, they have yet to reach their peak. It is crucial that we take action to reduce carbon emissions in order to mitigate the effects of climate change and protect our planet.

Annual CO2 emissions

Understanding Total Carbon Dioxide Emissions

Carbon dioxide (CO₂) emissions are a major contributor to climate change, and understanding their impact and trends is crucial for addressing the issue. This chart shows the growth of global CO₂ emissions from the mid-18th century to today.

Before the Industrial Revolution, emissions were very low. However, emissions began to increase rapidly in the mid-19th century, coinciding with global emissions reaching 3 billion tonnes of CO₂ in 1850. By 1950, emissions had almost quadrupled, reaching more than 22 billion tonnes. Today, we emit over 34 billion tonnes of CO₂ each year.

Although emissions growth has slowed in recent years, they have yet to reach their peak. It is crucial that we take action to reduce carbon emissions in order to mitigate the effects of climate change and protect our planet.

Annual CO2 emissions

Country	Year	Total	Coal	Oil	Gas	Cement	Flaring

2.4.6.PerCapitaEmission page table

Per Capita CO2 Emissions Across the World

Pier capita CO₂ emissions are the CO₂ emissions produced by the average citizen of a particular country. To calculate per capita emissions, the total emissions of a country are divided by its population. By examining per capita emissions across the world, we can gain insight into the level of inequality in carbon emissions that exists.

The disparity in per capita emissions across the globe is substantial. The major oil-producing countries tend to be the largest per capita CO₂ emitters, due to their relatively low populations. For instance, in 2017, Qatar had the highest emissions at 49 tonnes (t) per person, followed by Trinidad and Tobago (30), Kuwait (25), United Arab Emirates (25), Brunei (24),
